

# Imprecise probability for non-commuting observables

Armen E. Allahverdyan

Yerevan Physics Institute, Alikhanian Brothers Street 2, Yerevan 375036, Armenia

It is known that non-commuting observables in quantum mechanics do not have joint probability. This statement refers to the precise (additive) probability model. I show that the joint distribution of any non-commuting pair of variables can be quantified via upper and lower probabilities, i.e. the joint probability is described by an interval instead of a number (imprecise probability). I propose transparent axioms from which the upper and lower probability operators follow. They depend only on the non-commuting observables and revert to the usual expression for the commuting case.

PACS numbers: 03.65.-w, 03.67.-a

Non-commuting observables in quantum mechanics do not have a joint probability [1–5] [see section 1.1 of the Supplementary Material for a reminder]. This is the departure point of quantum mechanics from classical probabilistic theories [6]; it lies in the core of all quantum oddities. There are various quasi-probabilities (e.g., Wigner function) which have features of joint probability for (loosely defined) semiclassical states [7, 8, 12]. Quasi-probabilities do have two problems: (i) they (must) get negative for a class of quantum states, thereby preventing *any* probabilistic interpretation for them <sup>1</sup>. (ii) Even if the quasi-probability is positive on a certain state, it is not unique, i.e. there can be other (equally legitimate) quasi-probability that is positive (and has other expected features of probability) on this state, e.g. in quantum optics there is Wigner function, P-function, Terletsky-Margenau-Hill function *etc.* Despite of the drawbacks, quasi-probabilities do have many applications [7–11], since they still possess certain features of joint probability, e.g. they reproduce the marginals [2, 4, 7, 8, 11]. One can relax this requirement <sup>2</sup>, as done for joint measurements of non-commuting variables [4, 5, 17–20]. Such measurements have to be approximate, since they operate on an arbitrary initial state [4, 5]. They produce positive probabilities for the measurement results, but it is not clear to which extent these probabilities are intrinsic [21], i.e. to which extent they characterize the system itself, and not approximate measurements employed. Alternatively, one can consider two consecutive measurements of the non-commuting observables [22, 23]. These two-time probabilities do not (generally) qualify for the joint probability of the non-commuting observables; see section 1.2 of the Supplementary Material.

It is assumed that the sought joint probability is linear over the state (density matrix). If this condition is skipped, there are positive probabilities that correctly reproduce marginals for non-commuting observables [16, 20], e.g. simply the product of two marginals [12]. However, they do not reduce to the usual form of the joint quantum probability for *commuting* observables <sup>3</sup>; hence their physical meaning is unclear [12].

The statement on the non-existence of joint probability concern the usual *precise and additive* probability. This is not the only model of uncertainty. It was recognized since early days of probability theory [43] that the probability need not be precise: instead of being a definite number, it can be a definite interval [44–47]; see [48] for an elementary introduction.

Instead of a precise probability for an event  $E$ , the measure of uncertainty is now an interval  $[p(E), \bar{p}(E)]$ , where  $0 \leq p(E) \leq \bar{p}(E)$  are called lower and upper probabilities, respectively. Qualitatively,  $p(E)$  ( $1 - \bar{p}(E)$ ) is a measure of a sure evidence in favor (against) of  $E$ . The event  $E$  is surely more probable than  $E'$ , if  $p(E) \geq \bar{p}(E')$ . The usual probability is recovered for  $p(E) = \bar{p}(E)$ . Two different pairs  $[p(E), \bar{p}(E)]$  and  $[p'(E), \bar{p}'(E)]$  can hold simultaneously (i.e they are consistent), provided that  $p'(E) \leq p(E)$  and  $\bar{p}'(E) \geq \bar{p}(E)$  for all  $E$ . In particular, every imprecise probability is consistent with  $p'(E) = 0, \bar{p}'(E) = 1$ .

It is not assumed that for all  $E$  there is a true (precise, but unknown) probability that lies in  $[p(E), \bar{p}(E)]$ . This assumption is frequently (but not always [28]) made in applications [45, 46], and it did motivate the generalized Kolmogorovian axiomatics of imprecise probability [47]; see section 2.1 of the Supplementary Material. Imprecise joint probabilities in quantum mechanics are to be regarded as fundamental entities, not reducible to a lack of knowledge. They do need an independent axiomatic ground.

<sup>1</sup> Negative probabilities were not found to admit a direct physical meaning [13] (what can be less possible, then the impossible?). In certain cases what seemed to be a negative probability was later on found to be a local value of a physical quantity, i.e. physically meaningful, but not a probability [13]. Mathematical meaning of negative probability is discussed in Refs. [14, 15].

<sup>2</sup> Employing instead the unbiasedness: the averages of the non-commuting quantities are reproduced correctly [18].

<sup>3</sup> Given two projectors  $P$  and  $Q$  and state  $\rho$ , this product is  $\text{tr}(\rho P) \text{tr}(\rho Q)$ , while the correct form for  $PQ = QP$  is  $\text{tr}(\rho PQ)$ .

My purpose here is to propose a transparent set of conditions (axioms) that lead to quantum lower and upper joint probabilities. They depend only on the involved non-commuting observables (and on the quantum state).

*Previous work.* In 1967 Prugovecki tried to describe the joint probability of two non-commuting observables in a way that resembles imprecise probabilities [24]. But his expression was not correct (it still can be negative) [12]; see also [14] in this context. In 1991 Suppes and Zanotti proposed a local upper probability model for the standard setup of Bell inequalities (two entangled spins) [25]; see also [26, 27]. The formulation was given in the classical event space of hidden variables, and it is not unique even for the particular case considered. It violates classical observability conditions for the imprecise probability [25, 28, 47]. In particular, no lower probability exists in this scheme. Despite of such drawbacks, the pertinent message of [25] is that one should attempt at quantum applications of the upper probabilities that go beyond its classical axioms. More recently, Galvan attempted to employ (classical) imprecise probabilities for describing quantum dynamics in configuration space [31]. For a general discussion on quantum versus classical probabilities see [32].

*Notations.* All operators (matrices) live in a finite-dimensional Hilbert space  $\mathbb{H}$ . For two hermitean operators  $Y$  and  $Z$ ,  $Y \geq Z$  (larger or equal) means that all eigenvalues of  $Y - Z$  are non-negative, i.e.  $\langle \psi | (Y - Z) | \psi \rangle \geq 0$  for any  $|\psi\rangle \in \mathbb{H}$ . The direct sum  $Y \oplus Z$  of two operators refers to the block-diagonal matrix:  $Y \oplus Z = \begin{pmatrix} Y & 0 \\ 0 & Z \end{pmatrix}$ . The range  $\text{ran}(Y)$  of  $Y$  is the subspace of vectors  $Y|\psi\rangle$ , where  $|\psi\rangle \in \mathbb{H}$ . For orthogonal (sub)spaces  $\mathbb{A}$  and  $\mathbb{B}$ , the space  $\mathbb{A} \oplus \mathbb{B}$  is formed by all vectors  $|a\rangle + |b\rangle$ , where  $|a\rangle \in \mathbb{A}$  and  $|b\rangle \in \mathbb{B}$ .  $I$  is the unity operator of  $\mathbb{H}$ .  $I_n$  and  $0_n$  are the  $n \times n$  unity and zero matrices, respectively.

*Axioms for quantum imprecise probability.* Existing axioms for imprecise probability are formulated on a classical event space with usual notions of con- and disjunction and complementation [44, 44–47]; see section 2 of the Supplementary Material for a reminder. For quantum probability it is natural to start from a Hilbert space and introduce upper and lower probabilities as operators. The axioms below require only the most basic feature of upper and lower probability and demand its consistency with the quantum joint probability whenever the latter is well-defined.

The usual quantum probability can be defined over (hermitean) projectors  $P = P^2$  [33, 34]. A projector generalizes the classical notion of characteristic function. Each  $P$  uniquely relates to its eigenspace  $\text{ran}(P)$ .  $P$  refers to a set of hermitean operators  $\{\mathcal{P}\}$ :

$$[P, P] \equiv \mathcal{P}P - P\mathcal{P} = 0. \quad (1)$$

$P$  is a projector to an eigenspace of  $\mathcal{P}$  or to a direct sum of such eigenspaces, i.e.  $P$  refers to an eigenvalue of  $\mathcal{P}$  or to a union of several eigenvalues. The quantum (precise and additive) probability to observe  $P = 1$  is  $\text{tr}[\rho P]$ , where the density matrix  $0 \leq \rho \leq I$  defines the quantum state [4, 5, 33, 34].

Let  $Q$  be another projector which refers to the set  $\{\mathcal{Q}\}$  of observables. Generally,  $[P, Q] \neq 0$ . Given the density matrix  $\rho$ , we seek upper and lower joint probabilities of  $P$  and  $Q$  (i.e. of the corresponding eigenvalues of  $\mathcal{P}$  and  $\mathcal{Q}$ ):

$$\bar{p}(\rho; P, Q) = \text{tr}(\rho \bar{\omega}(P, Q)), \quad \underline{p}(\rho; P, Q) = \text{tr}(\rho \underline{\omega}(P, Q)), \quad (2)$$

where  $\underline{\omega}(P, Q)$  and  $\bar{\omega}(P, Q)$  are hermitean operators. Their dependence on  $P$  and  $Q$  can be expressed via Taylor series. We impose the following conditions (axioms):

$$0 \leq \underline{\omega}(P, Q) \leq \bar{\omega}(P, Q) \leq I, \quad (3)$$

$$\underline{\omega}(P, Q) = \underline{\omega}(Q, P), \quad \bar{\omega}(P, Q) = \bar{\omega}(Q, P), \quad (4)$$

$$\underline{\omega}(P, Q) = \bar{\omega}(P, Q) = PQ, \quad \text{if } [P, Q] = 0, \quad (5)$$

$$\text{tr}(\rho \underline{\omega}(P, Q)) \leq \text{tr}(\rho PQ) \leq \text{tr}(\rho \bar{\omega}(P, Q)), \quad \text{if } [P, \rho] = 0, \quad \text{or if } [\rho, Q] = 0. \quad (6)$$

$$[\omega(P, Q), Q] = [\omega(P, Q), P] = 0, \quad \omega = \underline{\omega}, \bar{\omega}. \quad (7)$$

Eq. (2) implies that  $\underline{p}$  and  $\bar{p}$  depend on  $\{\mathcal{P}\}$  and  $\{\mathcal{Q}\}$  only through  $P$  and  $Q$ . This non-contextuality feature holds also for the ordinary (one-variable) quantum probability [37, 38]. Provided that the operators  $\underline{\omega}$  and  $\bar{\omega}$  are found,  $\underline{p}$  and  $\bar{p}$  can be found in the usual way of quantum averages.

Conditions (3) stem from  $0 \leq \bar{p}(\rho; P, Q) \leq \underline{p}(\rho; P, Q) \leq 1$  that are demanded for all density matrices  $\rho$ . Eq. (4) is the symmetry condition necessary for the joint probability. Eq. (5) is reversion to the commuting case. In particular, (5) ensures  $\underline{\omega}(P, 0) = \bar{\omega}(P, 0) = 0$  and  $\underline{\omega}(P, I) = \bar{\omega}(P, I) = P$ . Since  $Q = I$  means that  $Q$  is anywhere, the latter equality is the reproduction of the marginal probability (which cannot be recovered by summation, since the probability model is not additive).

For  $[P, Q] = 0$  the joint probability is  $\text{tr}(\rho Q P) = \text{tr}(\rho P Q)$ . This expression is well-defined (i.e. positive, symmetric and additive) also for  $[\rho, Q] = 0$  or  $[\rho, P] = 0$  (but not necessarily  $[P, Q] = 0$ ). If  $[\rho, Q] = 0$ , one obtains  $\text{tr}(\rho Q P)$  by measuring  $Q$  ( $\rho$  is not disturbed) and then  $P$ . Alternatively, one can obtain it by measuring the average of an hermitean observable  $\frac{1}{2}(PQ + QP)$ . Thus (5, 6) demands that  $\bar{p}(\rho; P, Q)$  and  $\underline{p}(\rho; P, Q)$  are consistent with the joint probability  $\text{tr}(\rho P Q)$ , whenever the latter is well-defined.

Finally, (7) means that  $\omega(P, Q)$  ( $\omega = \underline{\omega}, \bar{\omega}$ ) can be measured *simultaneously and precisely* with  $P$  or with  $Q$  (on any quantum state), a natural condition for the joint probability (operators).

If there are several candidates satisfying (3–7) we shall naturally select the ones providing the largest lower probability and the smallest upper probability.

*CS-representation* will be our main tool. Given the projectors  $P$  and  $Q$ , Hilbert space  $\mathbb{H}$  can be represented as a direct sum [39–41] [see also section 3 of the Supplementary Material]

$$\mathbb{H} = \mathbb{H}' \oplus \mathbb{H}_{11} \oplus \mathbb{H}_{10} \oplus \mathbb{H}_{01} \oplus \mathbb{H}_{00}, \quad (8)$$

where the sub-space  $\mathbb{H}_{\alpha\beta}$  of dimension  $m_{\alpha\beta}$  is formed by common eigenvectors of  $P$  and  $Q$  having eigenvalue  $\alpha$  (for  $P$ ) and  $\beta$  (for  $Q$ ). Depending on  $P$  and  $Q$  every sub-space can be absent; all of them can be present only for  $\dim \mathbb{H} \geq 6$ . Now  $\mathbb{H}_{11} = \text{ran}(P) \cap \text{ran}(Q)$  is the intersection of the ranges of  $P$  and  $Q$ .  $\mathbb{H}'$  has even dimension  $2m$  [40, 41], this is the only sub-space in (8) that is not formed by common eigenvectors of  $P$  and  $Q$ . There exists a unitary transformation

$$P = U \hat{P} U^\dagger, \quad Q = U \hat{Q} U^\dagger, \quad U U^\dagger = I, \quad (9)$$

so that  $\hat{P}$  and  $\hat{Q}$  get the following block-diagonal form related to (8) [40]:

$$\hat{Q} = Q' \oplus I_{m_{11}} \oplus I_{m_{10}} \oplus 0_{m_{01}} \oplus 0_{m_{00}}, \quad Q' \equiv \begin{pmatrix} I_m & 0_m \\ 0_m & 0_m \end{pmatrix}, \quad (10)$$

$$\hat{P} = P' \oplus I_{m_{11}} \oplus 0_{m_{10}} \oplus I_{m_{01}} \oplus 0_{m_{00}}, \quad P' \equiv \begin{pmatrix} C^2 & CS \\ CS & S^2 \end{pmatrix}, \quad (11)$$

where  $C$  and  $S$  are invertible square matrices of the same size holding

$$C^2 + S^2 = I_m, \quad [C, S] = 0. \quad (12)$$

Now  $\text{ran}(P')$  and  $\text{ran}(Q')$  are sub-spaces of  $\mathbb{H}'$ . One has  $C = \cos T$  and  $S = \sin T$ , where  $T$  is the operator analogue of the angle between two spaces.  $\mathbb{H}_{m_{\alpha\beta}}$  are absent, if  $P$  and  $Q$  do not have any common eigenvector. This, in particular, happens in  $\dim(\mathbb{H}) = 2$ .

*The main result.* Note that if (3–7) holds for  $P$  and  $Q$ , they hold as well for  $\hat{P}$  and  $\hat{Q}$ , because  $\omega(P, Q) = U^\dagger \omega(\hat{P}, \hat{Q}) U$  for  $\omega = \underline{\omega}, \bar{\omega}$ . Section 4 of the Supplementary Material shows how to get  $\bar{\omega}(\hat{P}, \hat{Q})$  and  $\underline{\omega}(\hat{P}, \hat{Q})$  from (3–7) and (10, 11):

$$\bar{\omega}(\hat{P}, \hat{Q}) = \begin{pmatrix} C^2 & 0_m \\ 0_m & C^2 \end{pmatrix} \oplus I_{m_{11}} \oplus 0_{m_{10}+m_{01}+m_{00}}, \quad (13)$$

$$\underline{\omega}(\hat{P}, \hat{Q}) = 0_{2m} \oplus I_{m_{11}} \oplus 0_{m_{10}+m_{01}+m_{00}}. \quad (14)$$

Let  $g(P, Q) = g(Q, P)$  be the projector onto intersection  $\text{ran}(P) \cap \text{ran}(Q)$  of  $\text{ran}(P)$  and  $\text{ran}(Q)$ . We now return from (13, 14, 9) to original projectors  $P$  and  $Q$  [see section 4 of the Supplementary Material] and obtain the main formulas:

$$\underline{\omega}(P, Q) = g(P, Q), \quad (15)$$

$$\bar{\omega}(P, Q) = I - (P - Q)^2 - g(I - P, I - Q). \quad (16)$$

For  $[P, Q] = 0$ ,  $g(P, Q) = PQ$ , and we revert to  $\omega(P, Q) = \bar{\omega}(P, Q) = PQ$ . Note that  $[P, (P - Q)^2] = [Q, (P - Q)^2] = 0$ .

*Physical meaning of  $\underline{\omega}$  and  $\bar{\omega}$ .* When looking for a joint probability defined over two projectors  $P$  and  $Q$  one wonders whether it is just not some (operator) mean of  $P$  and  $Q$ . For ordinary numbers  $a \geq 0$  and  $b \geq 0$  there are 3 means: arithmetic  $\frac{a+b}{2}$ , geometric  $\sqrt{ab}$  and harmonic  $\frac{2ab}{a+b}$ . Now (15) is precisely the operator harmonic mean of  $P$  and  $Q$  [50]

$$g(P, Q) = 2P(P + Q)^- Q = 2Q(P + Q)^- P, \quad (17)$$

where  $A^-$  is the inverse of  $A$  if it exists, otherwise it is the pseudo-inverse; see section 5 of the Supplementary Material for various representations of  $\underline{\omega}(P, Q)$  and  $\overline{\omega}(P, Q)$ . More familiar formula is

$$g(P, Q) = \lim_{n \rightarrow \infty} Q(PQ)^n = \lim_{n \rightarrow \infty} P(QP)^n. \quad (18)$$

The intersection projector  $g(P, Q)$  appears in [33–37]. It was stressed that  $g(P, Q)$  cannot be a joint probability for non-commutative  $P$  and  $Q$  [17]. Its meaning is clear by now: it is the lower probability for  $P$  and  $Q$ .  $g(P, Q)$  is non-zero only if  $\text{tr}(P) \geq 2$  (or  $\text{tr}(Q) \geq 2$ ), since two different rays cross only at zero.

Let us now turn to  $\overline{\omega}$ . The transition probability between 2 pure states is determined by the squared cosine of the angle between them:  $|\langle \psi | \phi \rangle|^2 = \cos^2 \theta_{\psi\phi}$ . Eq. (13) shows that  $\overline{\omega}(P, Q)$  depends on  $C^2 = \cos^2 T$ , where  $T$  is the operator angle between  $\hat{P}$  and  $\hat{Q}$ . Note from (10, 11) that the eigenvalues  $\lambda$  of  $PQ$ , which hold  $0 < \lambda < 1$  are the eigenvalues of  $C^2$ , and—as seen from (13)—they are also (doubly-degenerate) eigenvalues of  $\overline{\omega}(P, Q)$ . Thus we have a physical interpretation not only for  $\text{tr}(PQ)$  (transition probability), but also for eigenvalues of  $PQ$  ( $PQ$  and  $QP$  have the same eigenvalues).

Eqs. (13, 14, 9) imply that the upper and lower probability operators can be measured simultaneously on any state [cf. (7)]:

$$[\underline{\omega}(P, Q), \overline{\omega}(P, Q)] = 0. \quad (19)$$

The operator  $\overline{\omega}(P, Q) - \underline{\omega}(P, Q)$  quantifies the uncertainty for joint probability, the physical meaning of this characteristics of non-commutativity is new.

Section 7 of the Supplementary Material calculates the upper and lower probabilities for several examples.

Note that the conditional (upper and lower) probabilities are straightforward to define, e.g. [cf. (2)]:  $\overline{p}(\rho; P|Q) = \overline{p}(\rho; P, Q)/\text{tr}(\rho Q)$ .

The distance between two probability intervals  $[\underline{p}, \overline{p}]$  and  $[\underline{p}', \overline{p}']$  can be calculated via the Hausdorff metric [49]

$$\max [|\underline{p} - \underline{p}'|, |\overline{p} - \overline{p}'|], \quad (20)$$

which nullifies if and only if  $\underline{p} = \underline{p}'$  and  $\overline{p} = \overline{p}'$ , and which reduces to the ordinary distance  $|p - p'|$  for usual (precise) probabilities. Now

$$\text{tr}(\rho \underline{\omega}(P_1, Q_1)) > \text{tr}(\rho \overline{\omega}(P, Q)), \quad (21)$$

means that the pair of projectors  $(P_1, Q_1)$  is surely more probable (on  $\rho$ ) than  $(P, Q)$ ; see section 7 of the Supplementary Material for examples. Note from (15, 16) that if

$$\text{tr}(\rho \omega(P, Q)) > \text{tr}(\rho \omega(I - P, I - Q)), \quad (22)$$

holds for  $\omega = \underline{\omega}$ , then it also holds for  $\omega = \overline{\omega}$  (and *vice versa*). Though in a weaker sense than (21), (22) means that  $P$  and  $Q$  together is more probable than neither of them together (which is the pair  $(I - P, I - Q)$ ). Eqs. (21, 22) are examples of comparative (modal) probability statements; see [30] in this context.

Further features of  $\underline{\omega}$  and  $\overline{\omega}$  are uncovered when looking at a monotonic change of their arguments; see section 6 of the Supplementary Material. Section 7 discusses concrete examples.

*Summary.* My main message is that while joint precise probability for non-commuting observables does not exist, there are well-defined expressions for upper and lower imprecise probabilities. They can have immediate applications as shown in section 7 of the Supplementary Material for simple examples. Not less important are the open question suggested by this research, e.g. what is the most convenient way of defining averages with respect to quantum imprecise probability, or are there even more general axioms that involve the density matrix non-linearity and reduce to the linear situation when (5, 6) (effective commutativity) holds.

I thank K.V. Hovhannisyan for discussions.

## SUPPLEMENTARY MATERIAL

### Imprecise probability for non-commuting observables by Armen E. Allahverdyan

This Supplementary Material consists of seven sections. All of them can be read independently from each other.

Sections 1, 2 and 3 recall, respectively, the no-go statements for the joint quantum probability, generalized axiomatics for the imprecise probability and the CS-representation. This material is not new, but is presented in a focused form, adapted from several different sources.

Section 4 contains the derivation of the main result, while sections 5 and 6 demonstrate various features of quantum imprecise probability.

Section 7 illustrates it with simple physical examples.

### 0. NOTATIONS

We first of all recall the employed notations. All operators (matrices) live in a finite-dimensional Hilbert space  $\mathbb{H}$ . For two hermitean operators  $Y$  and  $Z$ ,  $Y \geq Z$  means that all eigenvalues of  $Y - Z$  are non-negative, i.e.  $\langle \psi | (Y - Z) \psi \rangle \geq 0$  for any  $|\psi\rangle \in \mathbb{H}$ . The direct sum  $Y \oplus Z$  of two operators refers to the following block-diagonal matrix:

$$Y \oplus Z = \begin{pmatrix} Y & 0 \\ 0 & Z \end{pmatrix}.$$

$\text{ran}(Y)$  is the range of  $Y$  (set of vectors  $Y|\psi\rangle$ , where  $|\psi\rangle \in \mathbb{H}$ ).  $I$  is the unity operator of  $\mathbb{H}$ .  $\ker(Y)$  is the subspace of vectors  $|\phi\rangle$  with  $Y|\phi\rangle = 0$ .

$I_n$  and  $0_n$  are the  $n \times n$  unity and zero matrices, respectively.

In the direct sum of two sub-spaces,  $\mathbb{H} \oplus \mathbb{G}$  it is always understood that  $\mathbb{H}$  and  $\mathbb{G}$  are orthogonal. The vector sum of (not necessarily orthogonal) sub-spaces  $\mathbb{A}$  and  $\mathbb{B}$  will be denoted as  $\mathbb{A} + \mathbb{B}$ . This space is formed by all vectors  $|\psi\rangle + |\phi\rangle$ , where  $|\psi\rangle \in \mathbb{A}$  and  $|\phi\rangle \in \mathbb{B}$ .

## 1. NON-EXISTENCE OF (PRECISE) JOINT PROBABILITY FOR NON-COMMUTING OBSERVABLES

### 1.1 The basic argument

Given two sets of non-commuting hermitean projectors:

$$\sum_{k=1}^{n_P} P_k = I, \quad P_k P_i = \delta_{ik} P_k, \quad n_P \leq n, \quad (23)$$

$$\sum_{k=1}^{n_Q} Q_k = I, \quad Q_k Q_i = \delta_{ik} Q_k, \quad n_Q \leq n, \quad (24)$$

we are looking for non-negative operators  $\Pi_{ik} \geq 0$  such that for an arbitrary density matrix  $\rho$

$$\sum_{ik} \text{tr}(\rho \Pi_{ik}) = 1, \quad \sum_i \text{tr}(\rho \Pi_{ik}) = \text{tr}(\rho P_k), \quad \sum_k \text{tr}(\rho \Pi_{ik}) = \text{tr}(\rho Q_i). \quad (25)$$

These relations imply

$$\sum_{ik} \Pi_{ik} = I, \quad \Pi_{ik} \leq Q_i, \quad \Pi_{ik} \leq P_k. \quad (26)$$

Now the second (third) relation in (26) implies  $\text{ran}(\Pi_{ik}) \subseteq \text{ran}(Q_i)$  ( $\text{ran}(\Pi_{ik}) \subseteq \text{ran}(P_k)$ ). Hence  $\text{ran}(\Pi_{ik}) \subseteq \text{ran}(Q_i) \cap \text{ran}(P_k)$ .

Thus, if  $\text{ran}(Q_i) \cap \text{ran}(P_k) = 0$  (e.g. when  $P_k$  and  $Q_i$  are one-dimensional), then  $\Pi_{ik} = 0$ , which means that the sought joint probability does not exist.

If  $\text{ran}(Q_i) \cap \text{ran}(P_k) \neq 0$ , then the largest  $\Pi_{ik}$  that holds the second and third relation in (26) is the projection  $g(P_k, Q_i)$  on  $\text{ran}(Q_i) \cap \text{ran}(P_k) = 0$ . However, the first relation in (26) is still impossible to satisfy (for  $[P_i, Q_k] \neq 0$ ), as seen from the superadditivity feature (103):

$$\sum_{ik} g(P_i, Q_k) \leq \sum_k g(\sum_i P_i, Q_k) = \sum_k g(I, Q_k) = \sum_k Q_k = I. \quad (27)$$

### 1.2 Two-time probability (as a candidate for the joint probability)

Given (23, 24), we can carry out two successive measurements. First (second) we measure a quantity, whose eigen-projections are  $\{P_k\}$  ( $\{Q_i\}$ ). This results to the following joint probability for the measurement results [ $\rho$  is the density matrix]

$$\text{tr}(Q_i P_k \rho P_k). \quad (28)$$

Likewise, if we first measure  $\{Q_i\}$  and then  $\{P_k\}$ , we obtain a quantity that generally differs from (28):

$$\text{tr}(P_k Q_i \rho Q_i). \quad (29)$$

If we attempt to consider (29) [or (28)] as a joint additive probability for  $P_i$  and  $Q_k$ , we note that (29) [and likewise (28)] reproduces correctly only one marginal:

$$\sum_{i=1}^{n_Q} \text{tr}(Q_i P_k \rho P_k) = \text{tr}(P_k \rho), \quad \text{but} \quad \sum_{i=1}^{n_P} \text{tr}(Q_i P_k \rho P_k) \neq \text{tr}(Q_i \rho). \quad (30)$$

One can attempt to interpret the mean of (28, 29)

$$\mu(\rho; P_k, Q_i) = \frac{1}{2} [\text{tr}(P_k Q_i \rho Q_i) + \text{tr}(Q_i P_k \rho P_k)] = \text{tr}(\rho \frac{P_k Q_i P_k + Q_i P_k Q_i}{2}), \quad (31)$$

as a non-additive probability. This object is linear over  $\rho$ , symmetric (with respect to interchanging  $P_k$  and  $Q_i$ ), non-negative, and reduces to the additive joint probability for  $[P_k, Q_i] = 0$ . The relation  $\mu(\rho; P_k, I) = \text{tr}(\rho P_k)$  can be interpreted as consistency with the correct marginals (once  $\mu(\rho; P_k, Q_i)$  is regarded as a non-additive probability, there is no point in insisting that the marginals are obtained in the additive way).

However, the additive joint probability  $\text{tr}(\rho P_k Q_i)$  is well-defined also for  $[\rho, P_k] = 0$  (or for  $[\rho, Q_i] = 0$ ). If  $[\rho, P_k] = 0$  holds,  $\mu(\rho; P_k, Q_i)$  is not consistent with  $\text{tr}(\rho P_k Q_i)$ , i.e. depending on  $\rho$ ,  $P_k$  and  $Q_i$  both

$$\mu(\rho; P_k, Q_i) > \text{tr}(\rho P_k Q_i) \quad \text{and} \quad \mu(\rho; P_k, Q_i) < \text{tr}(\rho P_k Q_i) \quad (32)$$

are possible.

To summarize, the two-time measurement results do not qualify as the additive joint probability, first because they are not unique (two different expressions (28) and (29) are possible), and second because they do not reproduce the correct marginals. If we take the mean of two expressions (28) and (29) and attempt to interpret it as a non-additive probability, it is not compatible with the joint probability, whenever the latter is well-defined.

## 2. AXIOMS FOR CLASSICAL IMPRECISE PROBABILITY

### 2.1 Generalized Kolmogorov's axioms

Given the full set of events  $\Omega$ ,  $\overline{p}(\cdot)$  and  $\underline{p}(\cdot)$  defined over sub-sets  $A, B, \dots$  of  $\Omega$  (including the empty set  $\{0\}$ ) satisfy [45–47]:

$$\underline{p}(\{0\}) = 0, \quad (33)$$

$$\overline{p}(\Omega) = 1, \quad (34)$$

$$\overline{p}(A) = 1 - \underline{p}(\Omega - A), \quad (35)$$

$$\underline{p}(A \cup B) \geq \underline{p}(A) + \underline{p}(B), \quad \text{if } A \cap B = \{0\}, \quad (36)$$

$$\overline{p}(A \cup B) \leq \overline{p}(A) + \overline{p}(B), \quad \text{if } A \cap B = \{0\}, \quad (37)$$

where  $\Omega - A$  includes all elements of  $\Omega$  that are not in  $A$ , and where  $A \cap B$  means intersection of two sets;  $A \cap B = \{0\}$  holds for elementary events.

Here are some direct implications of (33–37).

$$A \supseteq B \implies \bar{p}(A) \geq \bar{p}(B), \quad (38)$$

$$\underline{p}(A) \geq \underline{p}(B). \quad (39)$$

Eq. (39) follows directly from (36). Eq. (38) follows from (36, 35). Next relation:

$$\bar{p}(A \cup B) \geq \bar{p}(A) + \underline{p}(B) \geq \underline{p}(A \cup B), \quad \text{if } A \cap B = 0, \quad (40)$$

which, in particular, implies

$$\bar{p}(A) \geq \underline{p}(A). \quad (41)$$

To derive (40), note that (36, 35) imply  $\bar{p}(\Omega - A - B) \leq \bar{p}(\Omega - A) - \underline{p}(B)$  or  $\bar{p}(\Omega - A) \geq \underline{p}(B) + \bar{p}(\Omega - A - B)$ , which is the first inequality in (40). The second inequality is derived via (37, 35).

The following inequality generalizes the known relation of the additive probability theory

$$\underline{p}(A) + \underline{p}(B) \leq \bar{p}(A \cup B) + \underline{p}(A \cap B) \quad (42)$$

To prove (42), we denote  $A' = A - A \cap B$ , which means  $A' \cap B = \{0\}$ . Now

$$\begin{aligned} \bar{p}(A \cup B) + \underline{p}(A \cap B) &= \bar{p}(A' \cup B) + \underline{p}(A \cap B) \\ &\geq \bar{p}(A') + \underline{p}(A \cap B) + \underline{p}(B) \end{aligned} \quad (43)$$

$$\geq \underline{p}(A) + \underline{p}(B) \quad (44)$$

where in (43) [resp. in (44)] we applied the first [resp. the second] inequality in (40).

Note that the (non-negative) difference  $\Delta p(A) = \bar{p}(A) - \underline{p}(A)$  between the upper and lower probabilities also holds the super-additivity feature (cd. (37))

$$\Delta p(A \cup B) \leq \Delta p(A) + \Delta p(B), \quad \text{if } A \cap B = 0. \quad (45)$$

Employing (40) one can derive [1] for arbitrary  $A_1$  and  $A_2$ :

$$\underline{p}(A_1 \cup A_2) + \underline{p}(A_1 \cap A_2) \leq \underline{p}(A_1) + \bar{p}(A_2) \leq \bar{p}(A_1 \cup A_2) + \bar{p}(A_1 \cap A_2), \quad (46)$$

$$\underline{p}(A_1) + \underline{p}(A_2) \leq \underline{p}(A_1 \cup A_2) + \bar{p}(A_1 \cap A_2) \leq \bar{p}(A_1) + \bar{p}(A_2), \quad (47)$$

$$\underline{p}(A_1) + \underline{p}(A_2) \leq \bar{p}(A_1 \cup A_2) + \underline{p}(A_1 \cap A_2) \leq \bar{p}(A_1) + \bar{p}(A_2). \quad (48)$$

## 2.2 Joint probability

The joint probabilities of  $A$  and  $B$  are now defined as

$$\underline{p}(A, B) = \underline{p}(A \cap B), \quad \bar{p}(A, B) = \bar{p}(A \cap B). \quad (49)$$

Employing the distributivity feature

$$(A_1 \cup A_2) \cap A_3 = (A_1 \cap A_3) \cup (A_2 \cap A_3), \quad (50)$$

which holds for any triple  $A_1, A_2, A_3$ , we obtain from (36, 37) for  $B \cap C = \{0\}$

$$\underline{p}(A, B \cup C) = \underline{p}((A \cap B) \cup (A \cap C)) \geq \underline{p}(A, B) + \underline{p}(A, C), \quad (51)$$

$$\bar{p}(A, B \cup C) = \bar{p}((A \cap B) \cup (A \cap C)) \leq \bar{p}(A, B) + \bar{p}(A, C). \quad (52)$$

### 2.3 Dominated upper and lower probability

The origin of (33–37) can be related to the *simplest* scheme of hidden variable(s) [45]. One imagines that there exists a precise probability  $P_\theta(A)$ , where the parameter  $\theta$  is not known. Only the extremal values over the parameter are known:

$$\bar{p}(A) = \max_\theta [P_\theta(A)], \quad \underline{p}(A) = \min_\theta [P_\theta(A)], \quad (53)$$

which satisfy (33–37).

However, it is generally not true that (33–37) imply the existence of a precise probability  $P_\theta(A)$  that holds (53) [46].

## 3. DERIVATION OF THE CS-REPRESENTATION

### 3.1 The main theorem

Let  $\mathbb{Q}'$  and  $\mathbb{P}'$  are two subspaces of Hilbert space  $\mathbb{H}'$  that hold ( $\mathbb{Q}'^\perp$  is the orthogonal complement of  $\mathbb{Q}'$ )

$$\mathbb{Q}' \cap \mathbb{P}' = 0, \quad \mathbb{Q}' \cap \mathbb{P}'^\perp = 0, \quad \mathbb{Q}'^\perp \cap \mathbb{P}' = 0, \quad \mathbb{Q}'^\perp \cap \mathbb{P}'^\perp = 0. \quad (54)$$

The simplest example realizing (54) is when  $\mathbb{Q}'$  and  $\mathbb{P}'$  are one-dimensional subspaces of a two-dimensional  $\mathbb{H}'$ .

Let  $\hat{Q}'$  and  $\hat{P}'$  be projectors onto  $\mathbb{Q}'$  and  $\mathbb{P}'$  respectively. Now  $I - \hat{Q}'$  is the projector of  $\mathbb{P}'^\perp$ , and let  $g(\hat{P}', \hat{Q}')$  be the projector  $\mathbb{Q}' \cap \mathbb{P}'$ . Employing the known formulas (see e.g. [41])

$$\text{tr}(\hat{Q} - g(\hat{Q}, I - \hat{P})) = \text{tr}(\hat{P} - g(\hat{P}, I - \hat{Q})), \quad (55)$$

we get from (54)

$$\dim \mathbb{P}' = \dim \mathbb{Q}' = \dim \mathbb{P}'^\perp = \dim \mathbb{Q}'^\perp = \frac{1}{2} \dim \mathbb{H}' = m, \quad (56)$$

which means that  $\dim \mathbb{H}'$  should be even for (54) to hold <sup>4</sup>.

Here is the statement of the CS-representation [40]: after a unitary transformation  $\hat{Q}'$  and  $\hat{P}'$  can be presented as

$$\hat{Q}' = \begin{pmatrix} I_m & 0_m \\ 0_m & 0_m \end{pmatrix}, \quad \hat{P}' = \begin{pmatrix} C^2 & CS \\ CS & S^2 \end{pmatrix}, \quad C^2 + S^2 = I_m, \quad \ker[C] = \ker[S] = 0, \quad (57)$$

where all blocks in (57) have the same dimension  $m$ .

To prove (57), note that  $\hat{Q}'$  and  $\hat{P}'$  can be written as [cf. (56)]

$$\hat{Q}' = \begin{pmatrix} I_m & 0_m \\ 0_m & 0_m \end{pmatrix}, \quad \hat{P}' = \begin{pmatrix} K' & B \\ B^\dagger & L \end{pmatrix}, \quad K' \geq 0, \quad L \geq 0, \quad \text{tr}(K' + L) = m. \quad (58)$$

Next, let us show that

$$\ker[B] = 0 \quad (59)$$

Since  $\hat{Q}'\hat{P}'(I - \hat{Q}') = \begin{pmatrix} 0_m & B \\ 0_m & 0_m \end{pmatrix}$ , we need to show that for any  $|\psi\rangle \in \mathbb{Q}'^\perp$ ,  $\hat{Q}'\hat{P}'|\psi\rangle = 0$  means  $|\psi\rangle = 0$ . Indeed, we have  $\hat{P}'|\psi\rangle \in \mathbb{Q}'^\perp$ , which together with  $\mathbb{Q}'^\perp \cap \mathbb{P}' = 0$  [see (54)] leads to  $|\psi\rangle = 0$ .

Eq. (59) implies that there is the well-defined polar decomposition [ $\hat{B}$  is hermitean, while  $V$  is unitary]

$$B = V\hat{B}, \quad \hat{B} = \sqrt{B^\dagger B} = \hat{B}^\dagger, \quad V = B(B^\dagger B)^{-1/2} = V^\dagger{}^{-1}. \quad (60)$$

---

<sup>4</sup> Eq. (56) can be derived by noting that  $\mathbb{Q}'^\perp \cap \mathbb{P}' = 0$  implies  $\ker(\hat{Q}'\hat{P}') = 0$ . Indeed, if  $Q|p\rangle = 0$ , where  $|p\rangle \in \mathbb{P}'$ , then  $\mathbb{Q}'^\perp \cap \mathbb{P}' \neq 0$ . Hence  $|p\rangle = 0$ . Let us mention for completeness that  $\text{ran}(\hat{Q}'\hat{P}') \cap \mathbb{Q}'^\perp = 0$ . Indeed, let us assume that  $|f\rangle \in \mathbb{Q}'$ ,  $|g\rangle \in \mathbb{P}'$  and  $\langle f|\hat{Q}'g\rangle = 0$ . Then  $\langle \hat{Q}'f|g\rangle = \langle f|g\rangle = 0$ . The last relation means that either  $f = 0$ , or  $\mathbb{Q}'^\perp \cap \mathbb{P}' \neq 0$ , which contradicts to (54).

We transform as

$$\begin{pmatrix} V^\dagger & 0_m \\ 0_m & I_m \end{pmatrix} \hat{Q}' \begin{pmatrix} V & 0_m \\ 0_m & I_m \end{pmatrix} = \hat{Q}', \quad \begin{pmatrix} V^\dagger & 0_m \\ 0_m & I_m \end{pmatrix} \hat{P}' \begin{pmatrix} V & 0_m \\ 0_m & I_m \end{pmatrix} = \begin{pmatrix} K & \hat{B} \\ \hat{B} & L \end{pmatrix}, \quad (61)$$

where  $K = V^\dagger V' U$ . We shall now employ the fact that the last matrix in (61) is a projector:

$$K = K^2 + \hat{B}^2, \quad L = L^2 + \hat{B}^2, \quad \hat{B} = \hat{B}K + L\hat{B}. \quad (62)$$

The first and second relations in (62) show that  $[K, \hat{B}] = [L, \hat{B}] = 0$ . Then the third relation produces  $\hat{B}(K+L-1) = 0$ . Since  $\hat{B} > 0$  (due to  $\ker(B) = 0$ ), we conclude that  $K+L = 1$ . The rest is obvious.

### 3.2 Joint commutant for two projectors

Given (57), we want to find matrices that commute both with  $\hat{P}'$  and  $\hat{Q}'$  [40]. Matrices that commute with  $\hat{Q}'$  read

$$\begin{pmatrix} X & 0_m \\ 0_m & Y \end{pmatrix}. \quad (63)$$

Employing (57), we get that (63) commutes with  $\hat{P}'$  if

$$XC^2 = C^2X, \quad (64)$$

$$YS^2 = S^2Y, \quad (65)$$

$$XCS = CSY. \quad (66)$$

Since  $C$  and  $S$  are invertible, (64, 65) imply that  $[X, S] = [X, C] = [Y, S] = [Y, C] = 0$ . And then (66) implies that  $X = Y$ . Hence

$$X = Y, \quad [X, C] = [X, S] = 0. \quad (67)$$

### 3.3 General form of the CS representation

The above derivation of (57) assumed conditions (54). More generally, the Hilbert space  $\mathbb{H}$  can be represented as a direct sum [39–41]

$$\mathbb{H} = \mathbb{H}' \oplus \mathbb{H}_{11} \oplus \mathbb{H}_{10} \oplus \mathbb{H}_{01} \oplus \mathbb{H}_{00}, \quad (68)$$

where the sub-space  $\mathbb{H}_{\alpha\beta}$  of dimension  $m_{\alpha\beta}$  is formed by common eigenvectors of  $P$  and  $Q$  having eigenvalue  $\alpha$  (for  $P$ ) and  $\beta$  (for  $Q$ ). Depending on  $P$  and  $Q$  every sub-space can be absent; all of them can be present only for  $\dim \mathbb{H} \geq 6$ . Now  $\mathbb{H}_{11} = \text{ran}(P) \cap \text{ran}(Q)$ .  $\mathbb{H}'$  has even dimension  $2m$  [40, 41], this is the only sub-space that is not formed by common eigenvectors of  $P$  and  $Q$ .

After a unitary transformation

$$P = U\hat{P}U^\dagger, \quad Q = U\hat{Q}U^\dagger, \quad UU^\dagger = I, \quad (69)$$

$\hat{P}$  and  $\hat{Q}$  get the following block-diagonal form that is related to (68) [40] and that generalizes (57):

$$\hat{Q} = Q' \oplus I_{m_{11}} \oplus I_{m_{10}} \oplus 0_{m_{01}} \oplus 0_{m_{00}}, \quad Q' \equiv \begin{pmatrix} I_m & 0_m \\ 0_m & 0_m \end{pmatrix}, \quad (70)$$

$$\hat{P} = P' \oplus I_{m_{11}} \oplus 0_{m_{10}} \oplus I_{m_{01}} \oplus 0_{m_{00}}, \quad P' \equiv \begin{pmatrix} C^2 & CS \\ CS & S^2 \end{pmatrix}, \quad (71)$$

where  $C$  and  $S$  are invertible square matrices of the same size holding

$$C^2 + S^2 = I_m, \quad [C, S] = 0. \quad (72)$$

$\mathbb{H}'$  refers to  $P'$  and  $Q'$ . If  $\hat{P}$  and  $\hat{Q}$  do not have any common eigenvector,  $\hat{P} = P'$  and  $\hat{Q} = Q'$ .

#### 4. DERIVATION OF THE MAIN RESULT (EQS. (15 , 16) OF THE MAIN TEXT)

We start with representation (70, 71) and axioms (3–7) of the main text. These axioms hold for  $\hat{P}$ ,  $\hat{Q}$  and  $\hat{\rho} = U\rho U^\dagger$  [see (69)] instead of  $P$ ,  $Q$  and  $\rho$ , because  $\omega(\hat{P}, \hat{Q}) = U^\dagger \omega(P, Q)U$  for  $\omega = \underline{\omega}, \overline{\omega}$  (recall that  $\underline{\omega}(\hat{P}, \hat{Q})$  and  $\overline{\omega}(\hat{P}, \hat{Q})$  are Taylor expandable). Hence we now search for  $\underline{\omega}(\hat{P}, \hat{Q})$  and  $\overline{\omega}(\hat{P}, \hat{Q})$ .

The block-diagonal form (70, 68) remains intact under addition and multiplication of  $\hat{P}$  and  $\hat{Q}$ . Hence  $\underline{\omega}(\hat{P}, \hat{Q})$  and  $\overline{\omega}(\hat{P}, \hat{Q})$  have the block-diagonal form similar to (70), where the diagonal blocks are to be determined. Let now  $\Pi_{\alpha\beta}$  be the projector on  $\mathbb{H}_{\alpha\beta}$ . We get  $[\alpha, \beta = 0, 1]$

$$\Pi_{\alpha\beta} \omega(\hat{P}, \hat{Q}) \Pi_{\alpha\beta} = \omega(\alpha, \beta) \Pi_{\alpha\beta}, \quad \omega = \underline{\omega}, \overline{\omega}. \quad (73)$$

Hence condition (5) of the main text implies [for  $\omega = \underline{\omega}, \overline{\omega}$  and  $\omega' = \underline{\omega}', \overline{\omega}'$ ]

$$\omega(\hat{P}, \hat{Q}) = \omega' \oplus I_{m_{11}} \oplus 0_{m_{10}+m_{01}+m_{00}}, \quad \omega' = \begin{pmatrix} \omega'_{11} & \omega'_{12} \\ \omega'_{12}^\dagger & \omega'_{22} \end{pmatrix}. \quad (74)$$

Aiming to apply (6) of the main text, we write down (70) explicitly as

$$\hat{Q} = \begin{pmatrix} I & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 & 0 \\ 0 & 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \quad (75)$$

The most general density matrix  $\hat{\rho}$  that commutes with  $\hat{Q}$  reads (in the same block-diagonal form)

$$\hat{\rho} = \begin{pmatrix} a_{11} & 0 & a_{12} & a_{13} & 0 & 0 \\ 0 & b_{11} & 0 & 0 & b_{12} & b_{13} \\ a_{12}^\dagger & 0 & a_{22} & a_{23} & 0 & 0 \\ a_{13}^\dagger & 0 & a_{23}^\dagger & a_{33} & 0 & 0 \\ 0 & b_{12}^\dagger & 0 & 0 & b_{22} & b_{23} \\ 0 & b_{13}^\dagger & 0 & 0 & b_{23}^\dagger & b_{33} \end{pmatrix}. \quad (76)$$

Now  $\hat{\rho}\hat{Q} = \hat{Q}\hat{\rho}$  is seen from the fact that after permutations of rows and columns,  $\hat{Q}$  and  $\hat{\rho}$  become  $I_{m+m_{11}+m_{10}} \oplus 0_{m+m_{01}+m_{00}}$  and  $a \oplus b$ , respectively. Note that  $a_{ii} \geq 0$  and  $b_{ii} \geq 0$ .

Eqs. (74, 75, 76) imply

$$\text{tr}(\hat{Q}\hat{\rho}\hat{P}) = \text{tr}(\hat{Q}\hat{\rho}\hat{Q}\hat{P}) = \text{tr}(C^2 a_{11} + a_{22}), \quad (77)$$

$$\text{tr}(\underline{\omega}(\hat{P}, \hat{Q})\hat{\rho}) = \text{tr}(\underline{\omega}'_{11} a_{11} + \underline{\omega}'_{22} a_{44} + a_{22}), \quad (78)$$

$$\text{tr}(\overline{\omega}(\hat{P}, \hat{Q})\hat{\rho}) = \text{tr}(\overline{\omega}'_{11} a_{11} + \overline{\omega}'_{22} a_{44} + a_{22}). \quad (79)$$

Condition (7) [of the main text] and (67) imply

$$\omega'_{11} = \omega'_{22}, \quad \omega'_{12} = 0, \quad \text{for } \omega' = \overline{\omega}', \underline{\omega}'. \quad (80)$$

Recall condition (6) of the main text. It amounts to  $(77) \geq (78)$  that should hold for arbitrary  $a_{ik}$  and  $b_{ik}$ . Hence we deduce:  $\underline{\omega}'_{22} = 0$  and hence  $\underline{\omega}'_{11} = \underline{\omega}'_{12} = 0$ . Likewise,  $(79) \geq (77)$  leads to  $\overline{\omega}'_{11} = \overline{\omega}'_{22} = C^2$ ,  $\overline{\omega}'_{12} = 0$ ; recall that we want the smallest upper probability. Now (4) [of the main text] holds, since

$$\begin{pmatrix} C^2 & 0_m \\ 0_m & C^2 \end{pmatrix} = \begin{pmatrix} I_m & 0_m \\ 0_m & I_m \end{pmatrix} - (P' - Q')^2. \quad (81)$$

Thus [cf. (68)]

$$\overline{\omega}(\hat{P}, \hat{Q}) = \begin{pmatrix} C^2 & 0_m \\ 0_m & C^2 \end{pmatrix} \oplus I_{m_{11}} \oplus 0_{m_{10}+m_{01}+m_{00}}, \quad (82)$$

$$\underline{\omega}(\hat{P}, \hat{Q}) = 0_{2m} \oplus I_{m_{11}} \oplus 0_{m_{10}+m_{01}+m_{00}}. \quad (83)$$

Now  $g(\hat{P}, \hat{Q}) = g(\hat{Q}, \hat{P})$  is the projector onto  $\text{ran}(\hat{P}) \cap \text{ran}(\hat{Q})$ . To return from (82, 83) to original projectors  $P$  and  $Q$ , we note via (70, 71) [recall that  $\Pi_{\alpha\beta}$  is the projector onto  $\mathbb{H}_{\alpha\beta}$ ]:

$$\Pi_{11} = g(\hat{P}, \hat{Q}), \quad \Pi_{10} = g(\hat{P}, I - \hat{Q}), \quad \Pi_{01} = g(I - \hat{P}, \hat{Q}), \quad \Pi_{00} = g(I - \hat{P}, I - \hat{Q}), \quad (84)$$

$$\underline{\omega}(\hat{P}, \hat{Q}) = g(\hat{P}, \hat{Q}), \quad (85)$$

$$P' = \hat{P} - g(\hat{P}, \hat{Q}) - g(\hat{P}, I - \hat{Q}), \quad (86)$$

$$Q' = \hat{Q} - g(\hat{P}, \hat{Q}) - g(\hat{Q}, I - \hat{P}), \quad (87)$$

$$\begin{aligned} \overline{\omega}(\hat{P}, \hat{Q}) &= I - g(\hat{P}, I - \hat{Q}) - g(I - \hat{P}, \hat{Q}) - g(I - \hat{P}, I - \hat{Q}) \\ &\quad - \left( P - Q - g(\hat{P}, I - \hat{Q}) + g(I - \hat{P}, \hat{Q}) \right)^2. \end{aligned} \quad (88)$$

We act back by  $U$ , e.g.  $g(\hat{P}, \hat{Q}) = U^\dagger g(P, Q)U$ , and get finally

$$\underline{\omega}(P, Q) = g(P, Q), \quad (89)$$

$$\overline{\omega}(P, Q) = I - (P - Q)^2 - g(I - P, I - Q). \quad (90)$$

## 5. REPRESENTATIONS OF UPPER AND LOWER PROBABILITY OPERATORS

### 5.1 Representations for the upper probability operator

Let us turn into a more detailed investigation of (90). Note from (70, 71, 84) that  $I - g(I - P, I - Q)$  is the projector to  $\text{ran}(P) + \text{ran}(Q)$ , where  $\text{ran}(P) + \text{ran}(Q)$  is the vector sum of two sub-spaces. Note the following representation [42]:

$$I - g(I - P, I - Q) = (P + Q)^-(P + Q) = (P + Q)(P + Q)^-, \quad (91)$$

where  $A^-$  is the pseudo-inverse of hermitean  $A$ , i.e. if  $A = V(a \oplus 0)V^\dagger$  (where  $V$  is unitary:  $VV^\dagger = I$ ), then  $A^- = V(a^{-1} \oplus 0)V^\dagger$ .

The third equality in (91) is the obvious feature of the pseudo-inverse. The first equality in (91) follows from the fact that  $(P + Q)^-(P + Q)$  is the projector on  $\text{ran}(P + Q)$  and the known relation [42]:

$$\text{ran}(P + Q) = \text{ran}(P) + \text{ran}(Q). \quad (92)$$

Employing  $(P - Q)^2 = I - (I - P - Q)^2$ ,  $\overline{\omega}(P, Q)$  can be presented as a function of  $P + Q$  [cf. (91)]:

$$\overline{\omega}(P, Q) = (I - P - Q)^2 - I + (P + Q)(P + Q)^-. \quad (93)$$

Note another representation for the projector to  $\text{ran}(P) + \text{ran}(Q)$  [34]

$$I - g(I - P, I - Q) = \min[A \mid A \geq Q, P], \quad (94)$$

where  $I - g(I - P, I - Q)$  equals to the minimal hermitean operator  $A$  that holds 2 conditions after |.

### 5.2 Representations for the lower probability operator

Let us first show that the projector  $g(P, Q)$  into  $\text{ran}(P) \cap \text{ran}(Q)$  holds [3]

$$g(P, Q) = 2P(P + Q)^-Q = 2Q(P + Q)^-P, \quad (95)$$

where  $A^-$  is the pseudo-inverse of  $A$  [cf. (91)].

The last equality in (95) follows from the fact that  $(Q + P)(P + Q)^-$  is the projector to  $\text{ran}(P) + \text{ran}(Q)$  [see (91, 92)], which then leads to  $P(Q + P)(P + Q)^- = (Q + P)(P + Q)^-P$ .

The first equality in (95) is shown as follows. Let  $|\psi\rangle \in \text{ran}(P) \cap \text{ran}(Q)$ . Then using (95):

$$2P(P + Q)^-Q|\psi\rangle = (P + Q)(P + Q)^-|\psi\rangle = |\psi\rangle.$$

Thus,  $\text{ran}(2P(P+Q)^{-}Q) \supseteq (\text{ran}(P) \cap \text{ran}(Q))$ . On the other hand,  $\text{ran}(2P(P+Q)^{-}Q) \subseteq \text{ran}(P)$  and  $\text{ran}(2P(P+Q)^{-}Q) \subseteq \text{ran}(Q)$ , where the first relation follows from the implication: if  $|\psi\rangle \notin \text{ran}(P)$ , then  $|\psi\rangle \notin \text{ran}(2P(P+Q)^{-}Q)$ .

There are two other (more familiar) representations of  $g(P, Q)$  [see e.g. [34, 42]]:

$$g(P, Q) = \lim_{n \rightarrow \infty} Q(PQ)^n, \quad (96)$$

$$= \max[A \mid 0 \leq A \leq Q, P]. \quad (97)$$

Eq. (96) can be interpreted as a result of (infinitely many) successive measurements of  $P$  and  $Q$ . Eq. (97) should be compared to (94).

Yet another representation is useful in calculations, since it explicitly involves a  $2 \times 2$  block-diagonal representation [3]:

$$P = \begin{pmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{pmatrix}, \quad Q = \begin{pmatrix} I_{n_1} & 0 \\ 0 & I_{n_2} \end{pmatrix}, \quad (98)$$

$$g(P, Q) = \begin{pmatrix} P_{11} - P_{12}P_{22}^{-}P_{21} & 0 \\ 0 & 0 \end{pmatrix}, \quad (99)$$

where  $P_{11}$ ,  $P_{12}$ ,  $P_{21}$  and  $P_{22}$  are, respectively,  $n_1 \times n_1$ ,  $n_1 \times n_2$ ,  $n_2 \times n_1$ ,  $n_2 \times n_2$  matrices.

### 5.3 Direct relation between the eigenvalues of $P - Q$ and $PQ$

We can now prove directly (i.e. without employing the CS representation) that there is a direct relation between the eigenvalues of  $\varpi(P, Q)$  and  $PQ$ . Let  $|x\rangle$  be the eigenvector of hermitean operator  $P - Q$ :

$$(P - Q)|x\rangle = \lambda|x\rangle, \quad (100)$$

where  $-1 \leq \lambda \leq 1$  is the eigenvalue. Multiplying both sides of (100) by  $P$  (by  $Q$ ) and using  $P^2 = P$  ( $Q^2 = Q$ ) we get

$$QP|x\rangle = (1 + \lambda)Q|x\rangle, \quad PQ|x\rangle = (1 - \lambda)P|x\rangle, \quad (101)$$

which then implies

$$PQ(P|x\rangle) = (1 - \lambda^2)(P|x\rangle), \quad QP(Q|x\rangle) = (1 - \lambda^2)(Q|x\rangle). \quad (102)$$

Thus  $P|x\rangle$  ( $Q|x\rangle$ ) is an eigenvector of  $PQ$  ( $QP$ ) with eigenvalue  $1 - \lambda^2$ .

As seen from (101), the 2d linear space  $\text{Span}(P|x\rangle, Q|x\rangle)$  formed by all superpositions of  $P|x\rangle$  and  $Q|x\rangle$  remains invariant under action of both  $\hat{P}$  and  $\hat{Q}$ . Together with  $\text{tr}(P - Q) = 0$  this means that if (100) holds, then  $P - Q$  has eigenvalue  $-\lambda$  with the eigen-vector living in  $\text{Span}(P|x\rangle, Q|x\rangle)$ .

Further details on the relation between  $PQ$  and  $P - Q$  can be looked up in [2].

## 6. ADDITIVITY AND MONOTONICITY

We discuss here the behavior of  $\underline{\omega}(P, Q)$  and  $\overline{\omega}(P, Q)$  [given by (89, 90)] with respect to a monotonic change of their arguments. For two projectors  $Q'$  and  $Q$ ,  $Q' \geq Q$  means  $Q' = Q + K$ , where  $K^2 = K$  and  $QK = 0$ . Now (89, 90) and (97) imply that  $\underline{\omega}(P, Q)$  is operator superadditive

$$\underline{\omega}(P, Q + K) \geq \underline{\omega}(P, K) + \underline{\omega}(P, Q). \quad (103)$$

Likewise,  $\overline{\omega}(P, Q)$  is operator subadditive, but under an additional condition:

$$\overline{\omega}(P, Q + K) \leq \overline{\omega}(P, K) + \overline{\omega}(P, Q), \quad \text{if } Q + K = I. \quad (104)$$

They are the analogues of classical features (36) and (37), respectively. Note that (103) and (36) are valid under the same conditions, since  $QK = 0$  is the analogue of  $A \cap B = \{0\}$ . In that sense the correspondence between (104) and (37) is more limited, since  $Q + K = I$  is more restrictive than  $QK = 0$ .

We focus on deriving (103), since (104) is derived in the same way. Note from (97) that  $g(P, Q) \leq Q$  and  $g(P, K) \leq K$  imply  $g(P, Q) + g(P, K) \leq Q + K$ . Since  $QK = 0$ ,  $g(P, Q) + g(P, K) \leq P$ . Using (97) for  $g(P, Q + K)$  we obtain (103).

Note as well that both  $\overline{\omega}(P, Q)$  and  $\underline{\omega}(P, Q)$  are monotonous [ $\omega = \underline{\omega}, \overline{\omega}$ ]:

$$\omega(P', Q') \geq \omega(P, Q), \quad \text{if } P' \geq P, Q \quad \text{and} \quad Q' \geq P, Q. \quad (105)$$

Eq. (105) for  $\omega = \underline{\omega}$  follows from (103). For  $\omega = \overline{\omega}$  it is deduced as follows [cf. (97, 94)]:

$$\overline{\omega}(P', Q') \geq \underline{\omega}(P', Q') = g(P', Q') \geq I - g(I - P, I - Q) \geq \overline{\omega}(P, Q). \quad (106)$$

Let us now discuss whether (104) can hold under the same condition  $QK = 0$  as (103). Now

$$\overline{\omega}(P, Q + K) \leq \overline{\omega}(P, Q) + \overline{\omega}(P, K), \quad (107)$$

amounts to

$$g(I - P, I - Q) + g(I - P, I - K) \leq I - P + g(I - P, I - Q - K). \quad (108)$$

First of all note that for  $Q + K = 1$  and  $QK = 0$  we get  $(I - Q)(I - K) = 0$  and (108) does hold for the same reason as (103).

For  $QK = 0$ , (108) is invalid in 3d space (as well as for larger dimensional Hilbert spaces). Indeed, let us assume that  $Q$  and  $K$  are 1d:

$$Q = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad K = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad (109)$$

Given  $I - P$  as

$$I - P = \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix} = \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{12}^* & a_{22} & a_{23} \\ a_{13}^* & a_{23}^* & a_{33} \end{pmatrix}, \quad (110)$$

we get [cf. (99)]

$$g(I - P, 1 - K) = \begin{pmatrix} a'_{11} & a'_{12} & 0 \\ a'_{21} & a'_{22} & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} a'_{11} & a'_{12} \\ a'_{21} & a'_{22} \end{pmatrix} = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} - \begin{pmatrix} a_{13} \\ a_{23} \end{pmatrix} a_{33}^- (a_{31} \ a_{32}),$$

where  $a_{33}^-$  is the pseudo-inverse of  $a_{33}$ .

Likewise,

$$g(I - P, I - Q) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & a'_{22} & a'_{23} \\ 0 & a'_{32} & a'_{33} \end{pmatrix}, \quad \begin{pmatrix} a'_{22} & a'_{23} \\ a'_{32} & a'_{33} \end{pmatrix} = \begin{pmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{pmatrix} - \begin{pmatrix} a_{21} \\ a_{31} \end{pmatrix} a_{11}^- (a_{12} \ a_{13}).$$

Now  $g(I - P, I - Q - K) = 0$ , since  $I - Q - K$  is a 1d projector. We can now establish that generically

$$g(I - P, I - Q) + g(I - P, I - K) \not\leq I \quad (111)$$

(let alone (108)), because the difference has both positive and negative eigenvalues.

The message (111) is that the function  $I - g(I - P, I - Q)$  is not sub-additive.

Now consider (107, 108), but under additional condition that  $PK = 0$ . Now (108) amounts to

$$g(I - P, I - Q) \leq K + g(I - P, I - Q - K), \quad (112)$$

which holds as equality since  $\text{ran}(K) \subseteq \text{ran}(P^\perp) \cap \text{ran}(Q^\perp)$ .

## 7. UPPER AND LOWER PROBABILITIES FOR SIMPLE EXAMPLES

### 7.1 Two-dimensional Hilbert space

It should be clear from (82, 83) that in two-dimensional Hilbert space, any lower probability operator  $\underline{\omega}(P, Q)$  is zero (since two rays overlap only at zero), while the upper probability operator  $\overline{\omega}(P, Q) = \overline{p}(\rho; P, Q)$  just reduces to the transition probability (i.e. to a number)  $\text{tr}(PQ)$ . Thus for the present case both  $\overline{p}$  and  $\underline{p}$  do not depend on  $\rho$ .

## 7.2 Spin 1

The  $3 \times 3$  matrices for the spin components read

$$L^x = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad L^y = \frac{i}{\sqrt{2}} \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, \quad L^z = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix}. \quad (113)$$

Now  $P_{\pm 1,0}^a$  for  $a = x, y, z$  are the one-dimensional projectors to the eigenspace with eigenvalues  $\pm 1$  or  $0$  of  $L^a$ :

$$P_1^x = \frac{1}{4} \begin{pmatrix} 1 & \sqrt{2} & 1 \\ \sqrt{2} & 2 & \sqrt{2} \\ 1 & \sqrt{2} & 1 \end{pmatrix}, \quad P_0^x = \frac{1}{2} \begin{pmatrix} 1 & 0 & -1 \\ 0 & 0 & 0 \\ -1 & 0 & 1 \end{pmatrix}, \quad P_{-1}^x = \frac{1}{4} \begin{pmatrix} 1 & -\sqrt{2} & 1 \\ -\sqrt{2} & 2 & -\sqrt{2} \\ 1 & -\sqrt{2} & 1 \end{pmatrix}, \quad (114)$$

$$P_1^y = \frac{1}{4} \begin{pmatrix} 1 & -i\sqrt{2} & -1 \\ i\sqrt{2} & 2 & -i\sqrt{2} \\ -1 & i\sqrt{2} & 1 \end{pmatrix}, \quad P_0^y = \frac{1}{2} \begin{pmatrix} 1 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 1 \end{pmatrix}, \quad P_{-1}^y = \frac{1}{4} \begin{pmatrix} 1 & i\sqrt{2} & -1 \\ -i\sqrt{2} & 2 & i\sqrt{2} \\ -1 & -i\sqrt{2} & 1 \end{pmatrix}, \quad (115)$$

$$P_1^z = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad P_0^z = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad P_{-1}^z = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad (116)$$

where the zero components are orthogonal to each other:

$$P_0^x P_0^y = P_0^x P_0^z = P_0^z P_0^y = 0. \quad (117)$$

Other overlaps are simple as well ( $\alpha \neq \beta$ )

$$\begin{aligned} \text{tr}(P_j^\alpha P_k^\beta) &= 1/4 \text{ if } j \neq 0 \text{ and } k \neq 0, \\ &= 1/2 \text{ if } j = 0 \text{ or } k = 0 \text{ but not both,} \\ &= 0 \text{ if } j = 0 \text{ and } k = 0. \end{aligned} \quad (118)$$

Given 2 projectors  $P$  and  $Q$ , we defined  $g(P, Q)$  as the projector on  $\text{ran}(P) \cap \text{ran}(Q)$ . For calculating  $g(P, Q)$  we employ (95). Here are upper probability operators for joint values of  $P^z$  and  $P^x$ :

$$\overline{\omega}(P_0^z, P_0^x) = 0, \quad (119)$$

$$\overline{\omega}(P_{\pm 1}^x, P_1^z) = \begin{pmatrix} \frac{1}{4} & 0 & 0 \\ 0 & \frac{1}{6} & \frac{\pm 1}{6\sqrt{2}} \\ 0 & \frac{\pm 1}{6\sqrt{2}} & \frac{1}{12} \end{pmatrix}, \quad (120)$$

$$\overline{\omega}(P_{\pm 1}^x, P_{-1}^z) = \begin{pmatrix} \frac{1}{12} & \frac{\pm 1}{6\sqrt{2}} & 0 \\ \frac{\pm 1}{6\sqrt{2}} & \frac{1}{6} & 0 \\ 0 & 0 & \frac{1}{4} \end{pmatrix}, \quad (121)$$

$$\overline{\omega}(P_0^x, P_{\pm 1}^z) = \begin{pmatrix} \frac{1}{2} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \frac{1}{2} \end{pmatrix}, \quad (122)$$

$$\overline{\omega}(P_{\pm 1}^x, P_0^z) = \begin{pmatrix} \frac{1}{4} & 0 & -\frac{1}{4} \\ 0 & \frac{1}{2} & 0 \\ -\frac{1}{4} & 0 & \frac{1}{4} \end{pmatrix}. \quad (123)$$

Since these are 1d projectors, all the lower probability operators nullify. Now (119) means that the precise probability of  $P_0^z$  and  $P_0^x$  is zero; cf. (117).

We now get from (119–123)

$$\sum_{k=\pm,0} \sum_{i=\pm,0} \overline{\omega}(P_k^x, P_i^z) = \begin{pmatrix} \frac{13}{6} & 0 & -\frac{1}{2} \\ 0 & \frac{5}{3} & 0 \\ -\frac{1}{2} & 0 & \frac{13}{6} \end{pmatrix}. \quad (124)$$

This matrix is larger than  $I$ , since its eigenvalues are  $\frac{8}{3}$ ,  $\frac{5}{3}$  and  $\frac{5}{3}$ .

Note from (70, 71) that for  $3 \times 3$  matrices  $\dim \mathcal{H}' = 2$ , while  $\dim \mathcal{H}_{11} = 1$  (if this sub-space is present at all). Hence the eigenvalues of  $\bar{\omega}$  relate to transition probabilities (118). Indeed, the eigenvalues of matrices in (120, 121) [resp. in (122, 123)] is  $(\frac{1}{4}, \frac{1}{4}, 0)$  [resp.  $(\frac{1}{2}, \frac{1}{2}, 0)$ ]. Hence the maximal probability interval  $[\frac{1}{4}, 0]$  that can be generated by (120, 121) is smaller than the maximal interval  $[\frac{1}{2}, 0]$  generated by (122, 123). As an example, let us take the upper probabilities generated on eigenstates of  $L^y$  ( $\epsilon, \eta, \chi = 1, 0, -1$ ):

$$\begin{aligned} \text{tr}[\bar{\omega}(P_\epsilon^x, P_\eta^z) P_\chi^y] &= 1/6 \text{ if } \epsilon\eta \neq 0, \\ &= 1/4 \text{ if } \epsilon\eta = 0, (1-\epsilon)(1-\eta) \neq 1, \chi \neq 0, \\ &= 1/2 \text{ if } \epsilon\eta = 0, (1-\epsilon)(1-\eta) \neq 1, \chi = 0, \\ &= 0 \text{ if } \epsilon = \eta = \chi = 0. \end{aligned} \quad (125)$$

Let us now turn to joint probabilities, where the lower probability is non-zero.

$$\underline{\omega}(P_0^x + P_{\pm 1}^x, P_1^z + P_0^z) = \begin{pmatrix} \frac{2}{3} & \pm \frac{\sqrt{2}}{3} & 0 \\ \pm \frac{\sqrt{2}}{3} & \frac{1}{3} & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \bar{\omega}(P_0^x + P_{\pm 1}^x, P_1^z + P_0^z) = \begin{pmatrix} \frac{3}{4} & \pm \frac{1}{2\sqrt{2}} & 0 \\ \pm \frac{1}{2\sqrt{2}} & \frac{1}{2} & 0 \\ 0 & 0 & \frac{1}{4} \end{pmatrix}, \quad (126)$$

$$\underline{\omega}(P_0^x + P_{\pm 1}^x, P_{-1}^z + P_0^z) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & \frac{1}{3} & \pm \frac{\sqrt{2}}{3} \\ 0 & \pm \frac{\sqrt{2}}{3} & \frac{2}{3} \end{pmatrix}, \quad \bar{\omega}(P_0^x + P_{\pm 1}^x, P_{-1}^z + P_0^z) = \begin{pmatrix} \frac{1}{4} & 0 & 0 \\ 0 & \frac{1}{2} & \pm \frac{1}{2\sqrt{2}} \\ 0 & \pm \frac{1}{2\sqrt{2}} & \frac{3}{4} \end{pmatrix}, \quad (127)$$

$$\underline{\omega}(P_1^x + P_{-1}^x, P_{\pm 1}^z + P_0^z) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \bar{\omega}(P_1^x + P_{-1}^x, P_{\pm 1}^z + P_0^z) = \begin{pmatrix} \frac{1}{2} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \frac{1}{2} \end{pmatrix}, \quad (128)$$

$$\underline{\omega}(P_0^x + P_{\pm 1}^x, P_1^z + P_{-1}^z) = \begin{pmatrix} \frac{1}{2} & 0 & -\frac{1}{2} \\ 0 & 0 & 0 \\ -\frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix}, \quad \bar{\omega}(P_0^x + P_{\pm 1}^x, P_1^z + P_{-1}^z) = \begin{pmatrix} \frac{3}{4} & 0 & -\frac{1}{4} \\ 0 & \frac{1}{2} & 0 \\ -\frac{1}{4} & 0 & \frac{3}{4} \end{pmatrix}, \quad (129)$$

$$\underline{\omega}(P_1^x + P_{-1}^x, P_1^z + P_{-1}^z) = \bar{\omega}(P_1^x + P_{-1}^x, P_1^z + P_{-1}^z) = \begin{pmatrix} \frac{1}{2} & 0 & \frac{1}{2} \\ 0 & 0 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix}. \quad (130)$$

Now  $\bar{\omega} - \underline{\omega}$  for (126, 127) has eigenvalues  $(\frac{1}{4}, \frac{1}{4}, 0)$ , while for (128, 129) this matrix has eigenvalues  $(\frac{1}{2}, \frac{1}{2}, 0)$  (the last case (130) refers to the commutative situation). Hence the probabilities for (128, 129) are more uncertain.

Next, let us establish whether certain combinations can be (surely) more probable than others. Note that

$$\text{Eigenvalues}[\underline{\omega}(P_0^x + P_{-1}^x, P_1^z + P_0^z) - \bar{\omega}(P_0^x + P_1^x, P_1^z + P_0^z)] = \left( \frac{\pm\sqrt{393}-3}{24}, -\frac{1}{4} \right). \quad (131)$$

Once there is (one) positive eigenvalue, there is a class of states  $\rho$  for which

$$\text{tr}(\rho \underline{\omega}(P_0^x + P_{-1}^x, P_1^z + P_0^z)) > \text{tr}(\rho \bar{\omega}(P_0^x + P_1^x, P_1^z + P_0^z)), \quad (132)$$

i.e.  $P^x = 0$  or  $-1$  and  $P^z = 0$  or  $1$  is more probable than  $P^x = 0$  or  $1$  and  $P^z = 0$  or  $1$ . Note that

$$[\underline{\omega}(P_0^x + P_{-1}^x, P_1^z + P_0^z), \bar{\omega}(P_0^x + P_1^x, P_1^z + P_0^z)] \neq 0. \quad (133)$$

Such examples can be easily continued, e.g.

$$\text{Eigenvalues}[\underline{\omega}(P_0^x + P_1^x, P_1^z + P_0^z) - \bar{\omega}(P_1^x + P_{-1}^x, P_1^z + P_0^z)] = \left( \frac{\pm\sqrt{57}-3}{12}, -\frac{1}{2} \right). \quad (134)$$
